SOUTH AFRICAN COMMERCIAL WHEAT QUALITY FOR THE 2006/2007 SEASON

Acknowledgements

With gratitude to:

- *The Winter Cereal Trust for its financial support in conducting this survey.*
- *The Grain Silo Industry and its members for their cooperation in providing the samples to make this survey possible.*
- *The National Chamber of Milling and its members for providing samples of wheat that were delivered directly to the mills.*

Introduction

The final calculated wheat production for the 2006/2007 season (2 105 000 tons) was 10 % better than the previous season (1 905 000 tons) and is also 10 % better than the 5-year average of 1 914 005 tons (2002/2003 to 2006/2007 seasons).

Although the hectolitre mass (78.4 kg/hl) and thousand kernel mass (37.2 g) were very good, this crop was of lower quality compared to the previous seasons.

About 10 % less samples made the grade B1 this season compared to other seasons. This was mainly because of the low protein levels.

The whole wheat protein averaged a ten year low with 11.45 % (12 % mb).

The quality of the flour was average to below average. The dough was of poorer quality than previous seasons with low alveogram and extensogram strengths. The farinogram development time of 3.4 minutes, was the shortest average ever experienced.

The straight-dough optimized 100-gram baking test, showed more variation in volume according to the protein content than in previous years.

Usually there are significant quality differences between the three major production regions, which was not evident with this season.

The Southern African Grain Laboratory (SAGL), receives samples from all the production areas, and determines the quality of the annual wheat crop. The results are then published in this report

and are also made available on the website www.sagl.co.za as raw data and an option to print the data in book format.

The SAGL has ISO 17025 accreditation and is also used as the reference laboratory for grain quality analyses in Southern Africa.

Samples, representing the production of each region, are fully graded and thousand kernel mass is done. Small samples are milled on the quadromat mill, after which a mixogram analysis is done.

Cultivar identification is done on these samples and sale figures of seed sold by the commercial grain silo owners are obtained.

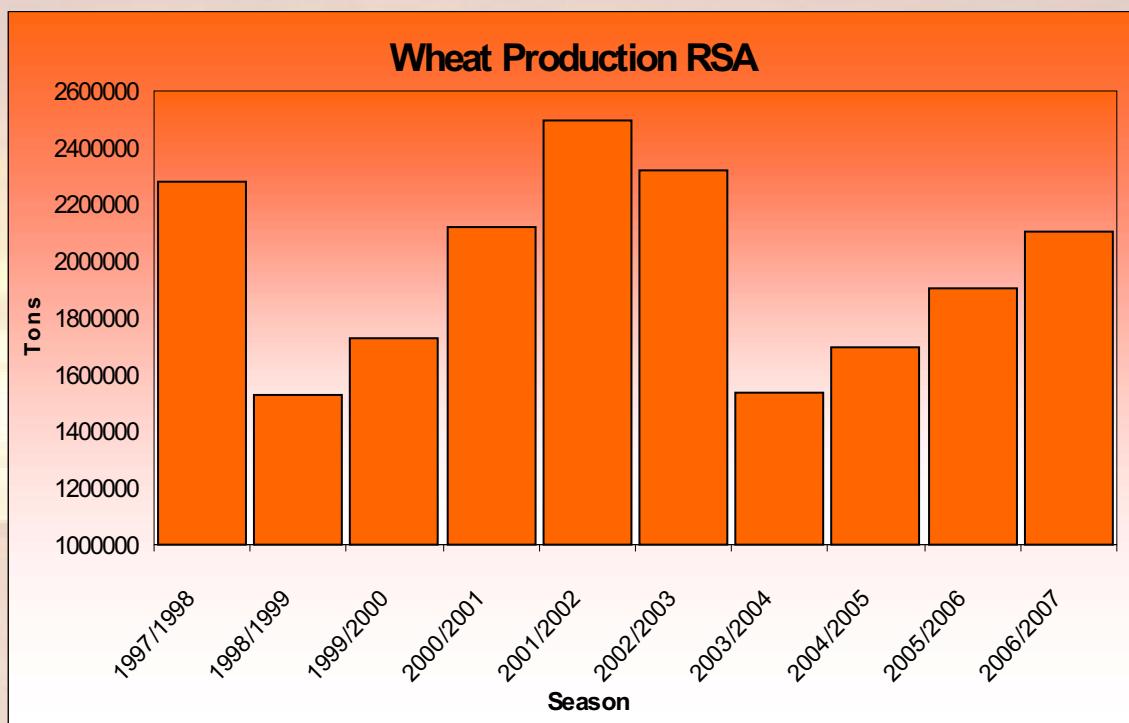

Composite samples are made up per class and grade for each production region and milled on the Bühler mill. Rheological tests, such as a mixogram, farinogram, alveogram, extensogram and 100-gram baking test, are then performed.

Imported wheat (1 October 2005 - 30 September 2006)

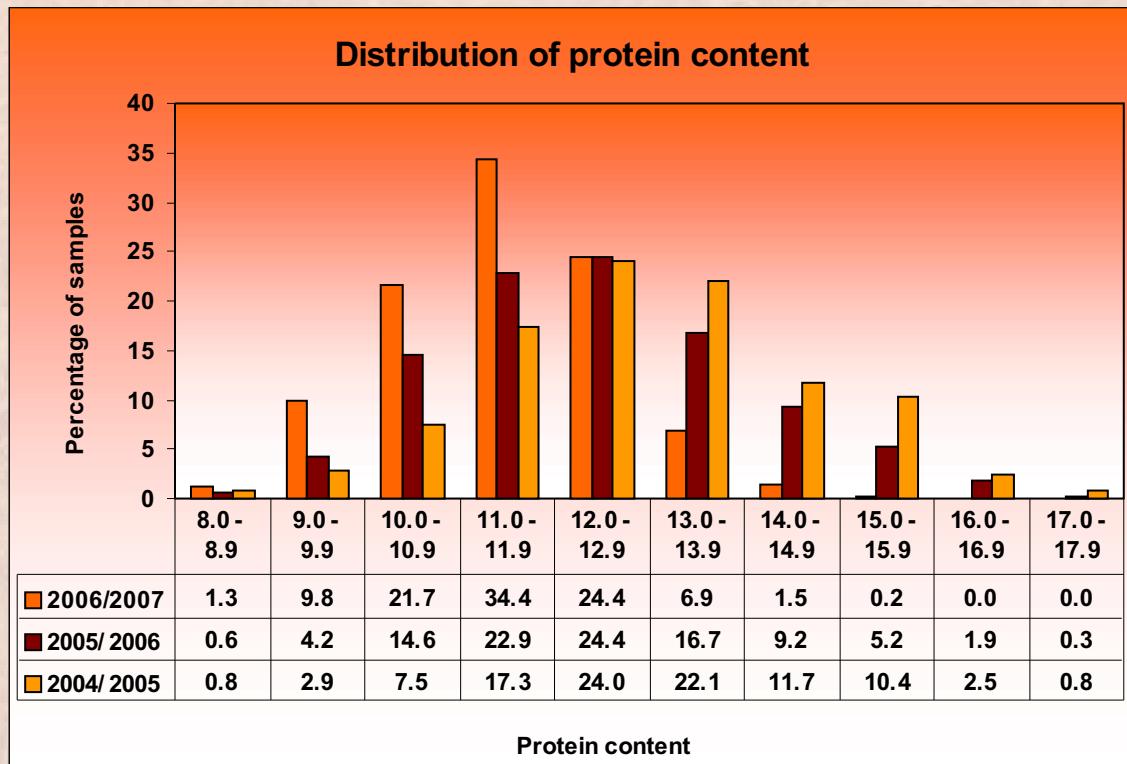

The SAGL is also monitoring the quality of all wheat imported into South Africa. The same analyses which are done on the local crop are also done on the imported wheat. The last sixteen pages of this report contain summaries of imported wheat from specific countries during the 2005/2006 season compared to a summary of the local crop quality for the same season. Summaries of the quality of the local wheat for the 2004/2005 and 2006/2007 season are also provided.

WHEAT PRODUCTION IN THE RSA OVER THE LAST 10 SEASONS

DIFFERENCES IN THE DISTRIBUTION OF PROTEIN CONTENT OVER THE LAST 3 SEASONS

Crop quality for 2006/2007 season

The protein average dropped to 11.5 % (12 % mb) (12.4 % in the previous season). The protein distribution graph of all the wheat produced was normal with most samples having protein contents between 10 % to 11.9 % (12 % mb).

The average hectolitre mass was 78.4 kg/hl (normal average). An average thousand kernel mass of 37.2 g was obtained.

The average screenings (1.8 mm sieve) was 1.81 %.

The average falling number was 351 seconds, there were six samples that gave falling number values of less than 220 seconds and eleven samples had falling number values of between 220 and 250 seconds. Falling number values less than 220 seconds is an indication of undesirable high enzyme activity that could have negative effects on the baking process.

The mixogram peak time on flour from the Quadromat mill averaged 2.8 minutes and is below the ten year average of 2.9 minutes. The mixogram peak time of the flour from the Bühler mill averaged 2.6 minutes.

The average Bühler extraction was 75.1 %, with an average Kent Jones colour of -1.2 KJ.

The farinogram had an average water absorption of 61.4 % (62.3 % the previous year) and an average development time of 3.4 minutes (5.0 minutes last season). The average alveogram strength was 36.8 cm² and the average P/L value 0.93 (40.7 cm² and 0.81 the previous season). The average extensogram strength was 82 cm² (108 cm² previous season).

The loaves baked using the 100 g straight-dough optimized bread making method, which refers to the relationship between the protein content and the bread volume, was evaluated from excellent to poor. The baking test with Free State (summer rainfall area) wheat flour scored the lowest with an average ranking of good, followed by the wheat flour from the Western Cape (winter rainfall areas) scoring an average ranking of very good with mostly the bread flour from the irrigation areas scoring an average ranking of excellent. This is the first survey that showed a wide variance in the bread volumes.

Quality of imported wheat for 2005/2006 season (previous season)

During the 2005/2006 season, 1 054 768 tons of wheat were imported to RSA. The biggest quantity was imported from Argentina, namely 392 930 tons, followed by Germany with 354 718 tons, then USA with 88 651 tons and Ukraine with 85 979 tons. Smaller quantities were imported from Canada (62 643 tons), Australia (59 927 tons) and France (9 920 tons). (SAGIS web site)

For grading as well as dough and baking quality of the imported wheat, please see pages 50 to 63.

Wheat grades

Representative samples (480) of the crop were graded as follows: 28 % was graded B1, 27 % was graded B2, 22 % was graded B3, 9 % was graded B4 and UT and COW made up 14 %. This year about 10 % less samples graded B1 compared to the previous year.

Grade B1 wheat in the Free State province amounted to 36 % and grade B1 in other summer rainfall areas amounted to 33 %. In the irrigation areas 31 % of the wheat graded as B1 and in the Western Cape Province only 17 % graded as B1.

Cultivars

In the winter rainfall area, SST 88 dominated the market. The Western Cape produced 33 % of all wheat grown in South Africa during the 2006/2007 season. In the Swartland area of the Western Cape, SST 88 (37 %) were followed by SST 027 (28 %) and SST 57 (16 %). In the Ruens area of the Western Cape, SST 88 (45 %) were followed by SST 57 (24 %) and SST 015 (14%).

The cultivar that dominated the market in the Free State was Elands (30 %). Elands was followed by Gariep (8%), SST 806 (7%) and PAN 3118 (6%).

The cultivar SST 806 (34 %) dominated the market in the Vaal and the Orange River areas, followed by CRN 826 with 29 % and SST 876 with 7 %.

In Limpopo and Gauteng SST 806 (42 %) was the dominant cultivar followed by CRN 826 (15%), SST 876 (14 %), Olifants (12 %) and SST 825 (11 %). The cultivar planted most in the Mpumalanga area was SST 806 (36 %) followed by CRN 826 (20 %), SST 876 (12 %) and Olifants (7 %).

The above information was calculated from the cultivar identification done on all 480 crop samples.

Mycotoxins

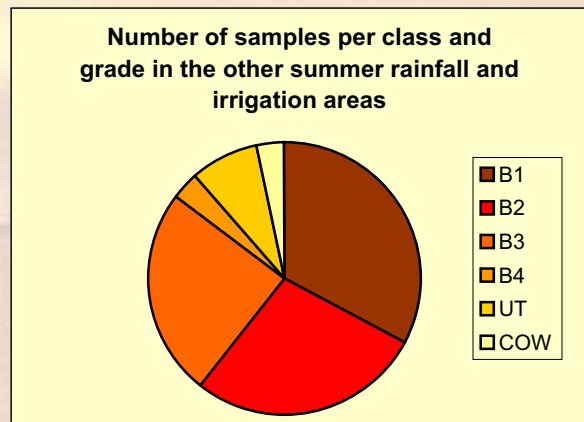

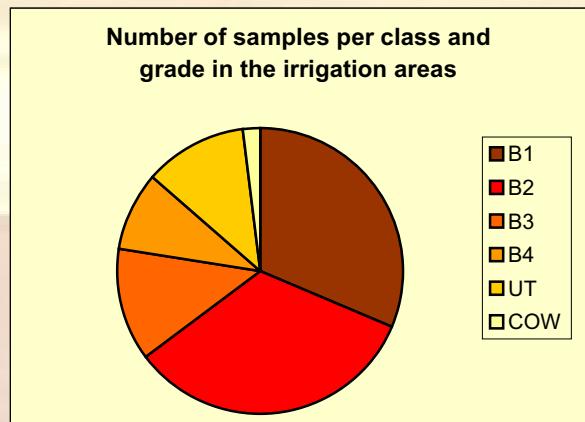

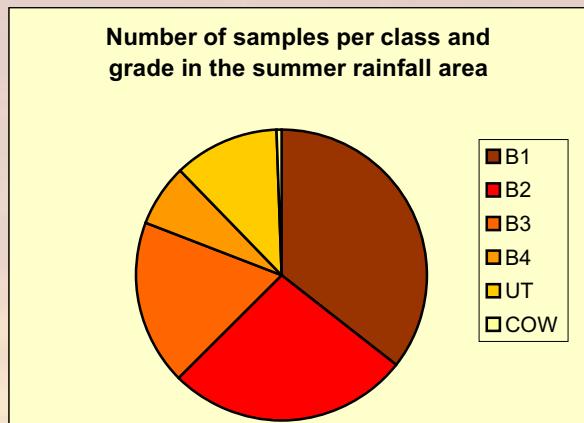

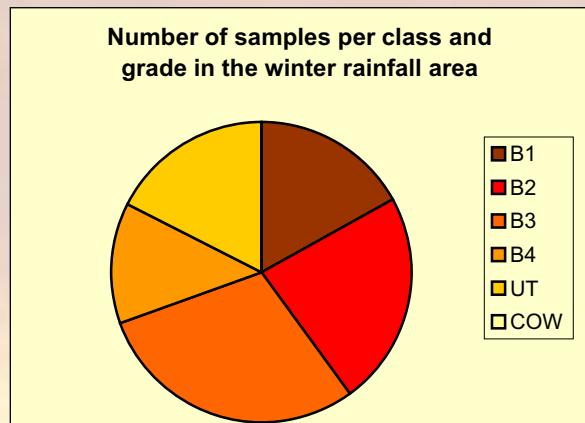

Mycotoxins, as secondary metabolites of moulds or fungi, can cause toxic effects in humans and animals consuming contaminated foods or feeds. Thirty samples (representing different regions) were selected randomly for mycotoxin analyses. These samples were tested for aflatoxin, deoxynivalenol and ochratoxin.

Tests are no longer done for T2, as the fungi producing this mycotoxin only grows at very low temperatures. As from the 2004/2005 season, the SAGL no longer tests for fumonisin and zearalenone, because the fungi producing these toxins do not grow on wheat.

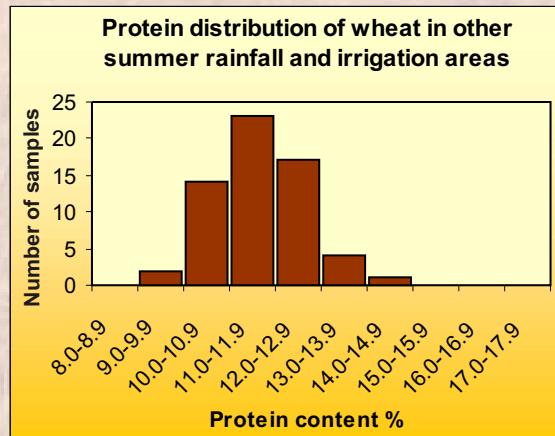

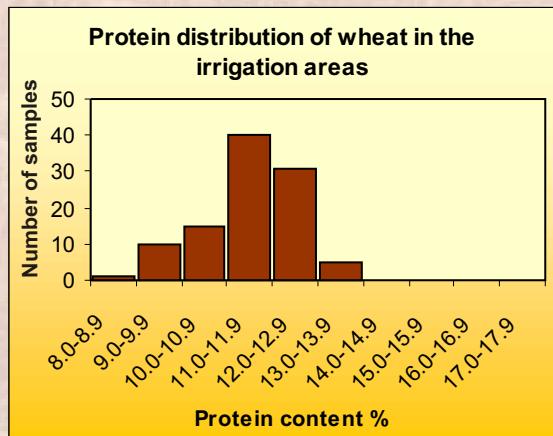

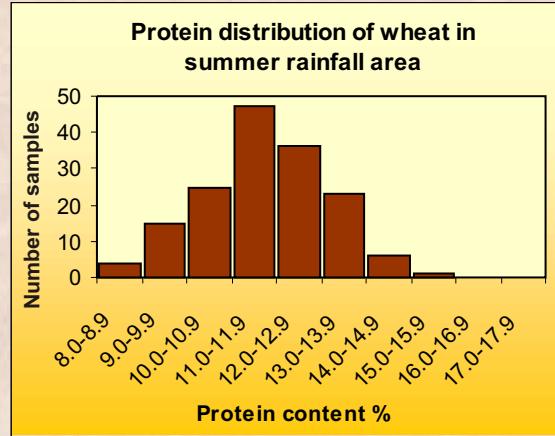

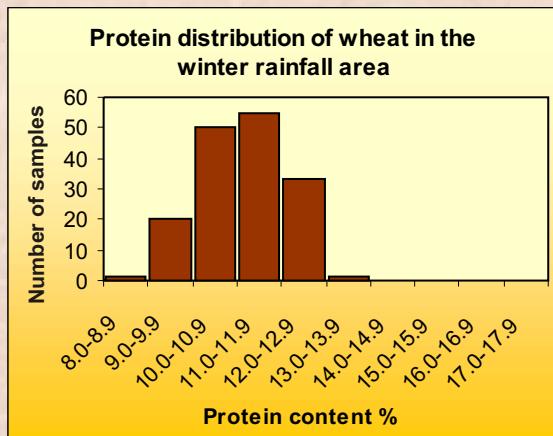

No aflatoxin was found on the 30 samples tested. In accordance with Act 54 of 1972, Foodstuffs, Cosmetics and Disinfectants, the allowable level of total aflatoxin is 10 ppb ($\mu\text{g}/\text{kg}$). In accordance with Act 36 of 1947, Fertilizers, Farm Feeds, Agricultural and Stock Remedies, the allowable level of total aflatoxin is 10 to 50 ppb ($\mu\text{g}/\text{kg}$).

Ochratoxin was found in six of the 30 samples tested ranging between 0.47 ppb to 1.4 ppb. In all samples tested, levels of deoxynivalenol were found, averaging 1.46 ppm, and ranging between 0.53 to 2.4 ppm.

AVERAGE QUALITY OVER 10 SEASONS

(1997/1998 no data available)

The horizontal line within each graph indicates the 10 year average.

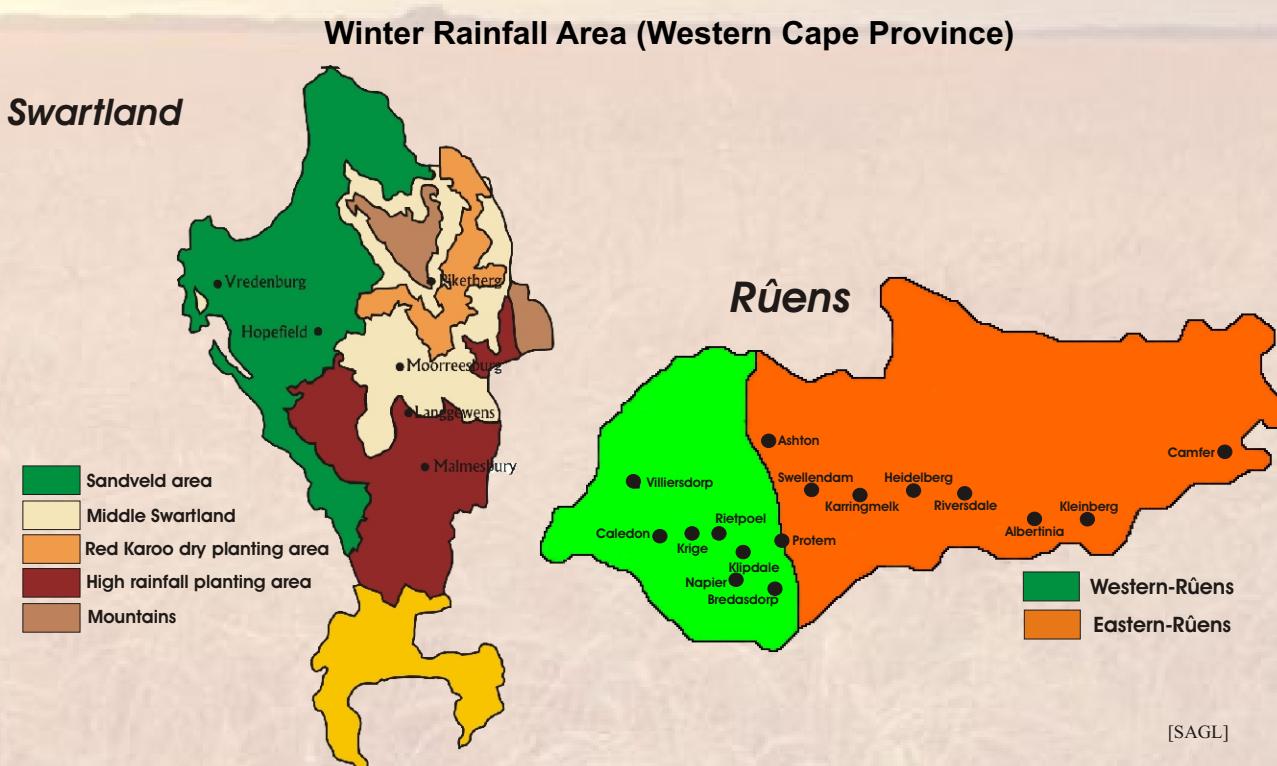

REGIONAL QUALITY

WINTER RAINFALL AREA (Western Cape)

Production regions 1 to 6 fall within the winter rainfall area (Western Cape Province). Regions 1 to 4 are the Swartland area and regions 5 and 6 the Rûens area. No samples were received from region 1 for this season. The Western Cape had the second highest production of all the provinces this season, namely 712 500 tons (CEC).

The hectolitre mass averaged 77.3 kg/hl (the previous season 78.5 kg/hl). The thousand kernel mass averaged 38.0 gram, which is better than the previous season's 35.8 gram. The Western Cape had a normal year regarding rainfall except for little rain in the Swartland area during harvest resulting in isolated cases of pre-harvest sprouting. The average falling number was 365 seconds.

The protein averaged 11.13 % (12 % mb) and is a little lower than the previous season (11.53 %). The average protein in the Swartland was 11.10 % (11.6 % the previous season) and the average protein in the Rûens was 11.20 % (the same as in 2005/2006). The hectolitre mass of the Swartland and Rûens was 77.8 kg/hl and 76.4 kg/hl respectively.

The screenings of 1.80 % were higher than the previous season's 1.53 %. The screenings in the Swartland averaged 1.83 % and that of the Rûens 1.74 %. The Bühler extraction averaged 74.8 % (average of wheat grades B1 to B4, UT and COW) and the average colour of the flour was -1.2 KJ units. Both these characteristics equaled that of the wheat in the Free State, but were not as good as the wheat from the other rainfall areas, and the Vaal and Orange River irrigated wheat.

The dough quality was the same as in the previous season. The mixogram peak time (Quadromat mill) averaged 2.6 minutes. The average farinogram absorption was 61.0 %. The average strength of the alveogram was 32.8 cm² and the average strength of the extensogram was 72 cm², compared to the Free State (89 cm²) and 80 cm² in the irrigation areas.

The 100-gram baking test showed a very good relationship between protein content and bread volume.

SUMMER RAINFALL AREA

(Free State)

Production regions 21 to 28, which fall within the Free State Province, had the second highest production, namely 810 000 tons (CEC).

The physical characteristics such as hectolitre mass (78.7 kg/hl), thousand kernel mass (35.9 gram) were better than the previous season's 77.5 kg/hl and 34.3 gram respectively. The screenings were higher (1.64 %) than the previous season's 1.50 %. The average protein dropped to 11.71 % (12 % mb) from an average of 13.95 % the previous season.

The Free State had normal weather conditions during spring and summer but Central Free State and the Eastern Free State experienced some rain during harvesting, which resulted in some samples with low falling number values as well as field fungi.

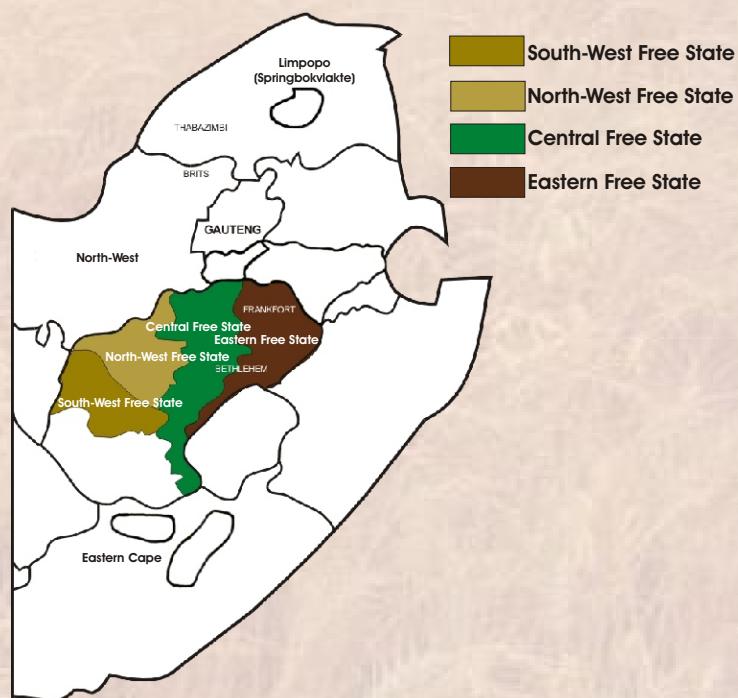

The mixogram (Quadromat) peak time was 3.0 minutes (3.1 minutes previous season), giving the Free State the longest average mixogram peak time of the different regional qualities.

The average Bühler extraction percentage in the Free State was the lowest in all the regions, namely 74.5 % (74.4 % previous season). The Kent Jones flour colour was -1.2 KJ units (-1.1 KJ units in previous season). The wheat of the Free State usually yields a little darker flour than the other regions but all three main producing areas yielded an average colour of -1.2 KJ units this season.

The average farinogram water absorption was 61.6 % (63.2 % the previous season), also the same as the other regions. The wheat from the Free State usually tends to give a stronger dough than the other regions, but averaged more or less the same than the other regions with a farinogram development time of 3.5 minutes, alveogram strength of 41.8 cm² and an extensogram strength of 89 cm².

The 100-gram baking test showed that the relationship between protein content and bread volume was ranging from good, questionable to poor, between the different grades.

FREE STATE

SUMMER RAINFALL AREA (Mpumalanga, Limpopo, Gauteng and Eastern Cape)

Other summer rainfall regions, excluding the Free State, are mainly regions 30, 32, 33 (Mpumalanga), 34 (Gauteng) and 35 (Limpopo). They produced in total about 192 300 tons during this season. No samples were received from the Eastern Cape or KwaZulu-Natal regions.

The average hectolitre mass was 79.1 kg/hl (78.4 kg/hl the previous season). This is more or less the same as in the irrigation areas. The thousand kernel mass was the second highest with an average of 37.8 g (winter rainfall area 38.0 g).

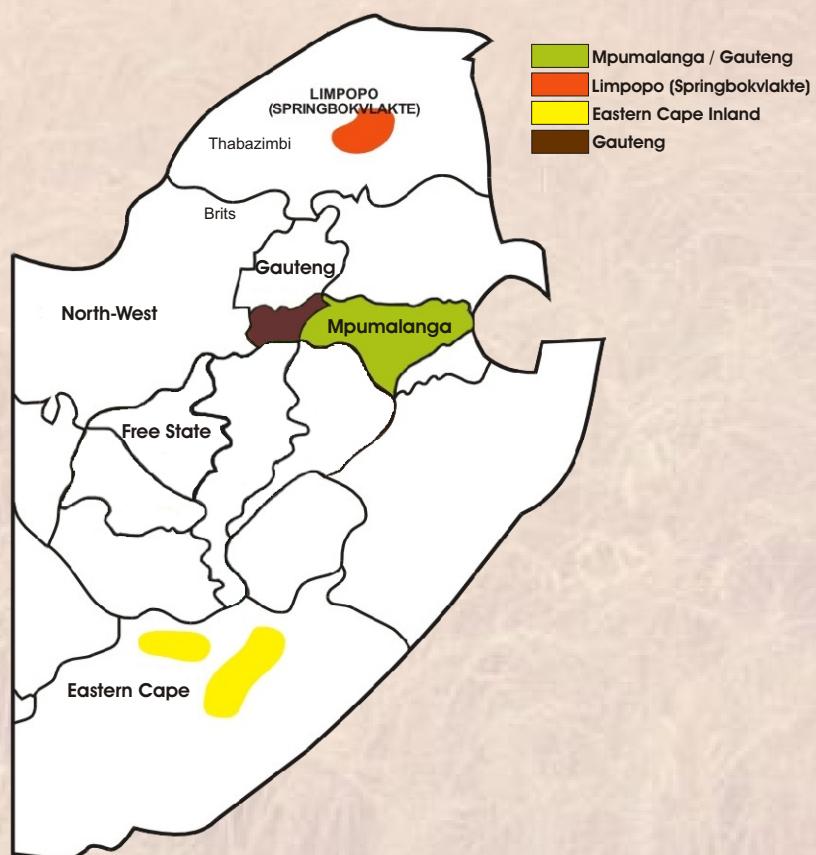

The average falling number was 358 seconds. The average percentage screenings was 2.0 %. The average protein content was 11.66 % (12 % mb), which is 0.8 % lower than the previous year.

The average mixogram (Quadromat) peak time was 2.7 minutes (2.8 minutes the previous season).

The average Bühler extraction was 75.6 %, with an average colour of -1.3 KJ units (76.4 % and -2.1 KJ units the previous season). The farinogram average water absorption was 61.8 % (62.4 % the previous season) and had an average development time of 3.5 minutes.

The average alveogram strength was 36.5 cm², with an average P/L value of 0.84, and the average extensogram strength was 86 cm².

The 100-gram baking test showed an excellent relationship between protein content and bread volume.

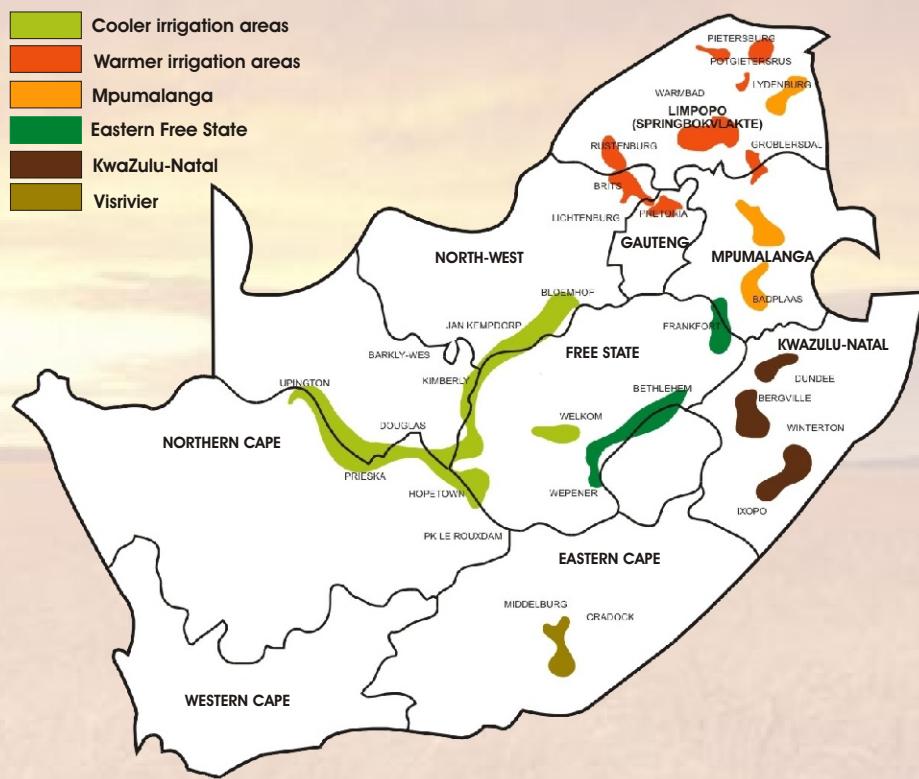

(Regional maps kindly provided by the Small Grains Institute, ARC)

IRRIGATION AREAS

(Vaal and Orange River plus other irrigation areas. See map.)

Irrigation areas in South Africa

The average hectolitre mass was 79.2 kg/hl (75.7 kg/hl the previous season) and the thousand kernel mass was 37.6 g (35.8 g the previous season). The average falling number was 358 seconds. The average screenings was 1.96 % and the protein averaged 11.46 % (12 % mb) and were both a little lower than the 2.06 % screenings and the 11.56 % (12 % mb) protein of the previous season.

The average mixogram (Quadromat) peak time was 2.6 minutes which was the same as the previous season.

The average Bühler extraction percentage was 75.6 (76.0 % in previous season), with an average flour colour of -1.2 KJ units.

The average farinogram water absorption was 61.2 % (61.9 % during previous season), with an average farinogram development time of 3.4 minutes.

The average alveogram strength was 35.1 cm² and the average P/L was 0.81 (37.9 cm² and 0.71 cm² respectively the previous season).

The average extensogram strength was 80 cm². The relationship between protein content and bread volume was shown to be excellent, very good and good by the 100-gram baking test.

South African Winter Cereal Production

Wheat is by far the biggest winter cereal crop planted in South Africa. Other winter crops are barley, canola and sweet lupines. Summer field crops are better suited for the South African climatic conditions. Maize being the largest of the different crops, followed by wheat, then sunflower seed, soybeans, barley, sorghum, dry beans, groundnuts, canola and sweet lupines. The annual South African wheat crop is about one quarter of the annual maize crop.

South Africa (made up of nine provinces) is divided into 36 crop production regions with wheat planted in about 32 of these regions. These production regions are described on pages 16 to 43 (on the top of the left page) giving the specific intake silo names for each region.

The three main wheat producing provinces are Free State (summer rainfall), Western Cape (winter rainfall) and the Northern Cape (irrigation). A fourth province worth mentioning is the North-West (mainly irrigation). See map on page 46.

The Free State province produced 810 000 tons and the Western Cape province followed with 712 500 tons. (Sixth estimate by the Crop Estimates Committee, CEC). These two provinces were responsible for 70 % of the total wheat produced.

The yield ranged from 6.2 tons per hectare in the Northern Cape (irrigation area) to 2.3 tons per hectare for the Free State (summer rainfall area). Other areas with high yields were Mpumalanga with 5.5 tons per hectare, Gauteng with 5.4 tons per hectare, North West with 5.0 tons per hectare and Limpopo and KwaZulu-Natal with each 4.5 tons per hectare dryland. All these “other” areas also produce irrigation wheat. The Western Cape area (2.5 tons per hectare) and Eastern Cape (3.5 tons per hectare) are dependant on winter rainfall. (CEC)

The total production is not enough for domestic requirements and South Africa has to import wheat to meet its domestic consumption of approximately 2.8 million tons every year.

South Africa has four major wheat-breeding programs. The wheat industry has set up a release criteria document with stringent quality evaluation norms. The South African breeders can only release a new cultivar or an introduction cultivar if it has better agronomical as well as better flour quality characteristics than the cultivars planted commercially in a specific area. Producers continuously try to improve the wheat yield and quality by selecting the best cultivars that can be grown commercially in a specific area. Grading standards are also set high to ensure adequate quality control.

Sampling procedure for the annual quality survey

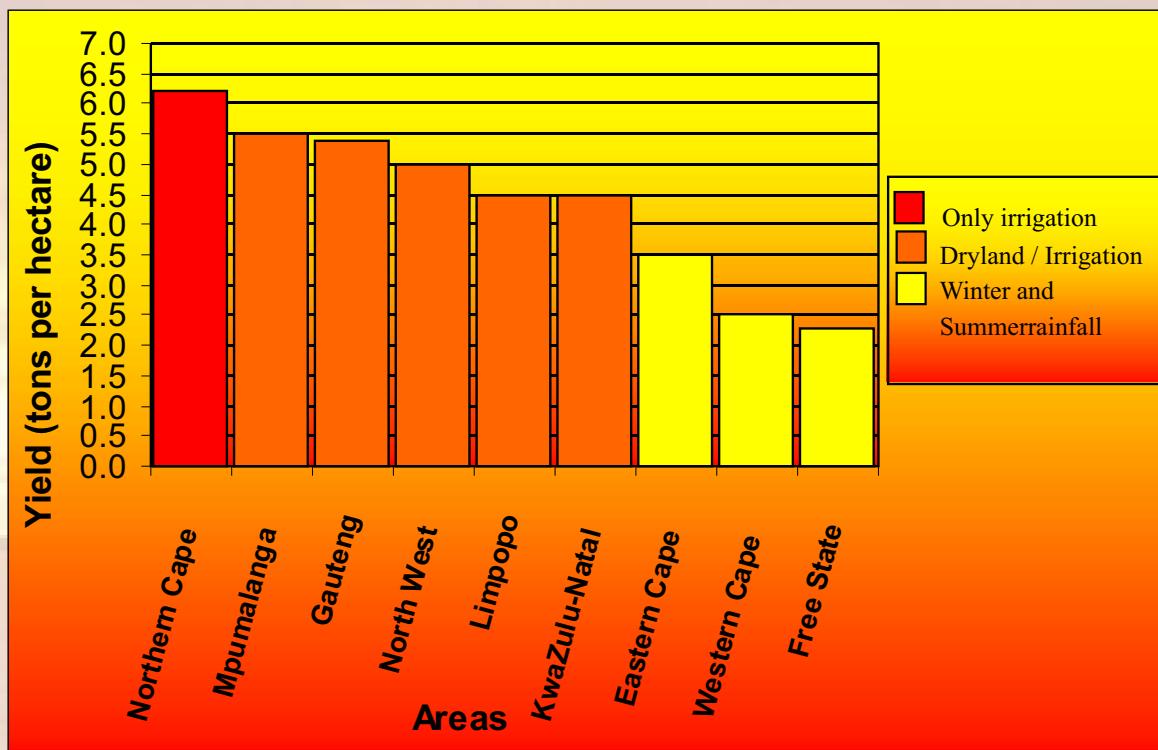

During the harvest season, a sample of each delivery of wheat is taken according to the prescribed Wheat regulation. A representative sample needs to be drawn for grading purposes before the wheat is taken in at the silo. Of each of these grading samples, about 200 grams is thrown into a 100 kg bin according to grade and class at each silo. The 100 kg bin is divided and a 5 kg sample is send to the SAGL for the annual quality survey.

The same method is followed where wheat is delivered directly from the producer to the miller.

After receiving these representative wheat crop samples from all over the country, the SAGL select 480 samples representing the wheat production of wheat for that specific region/province.

South Africa is the only wheat producing country known-of that produces this kind of comprehensive quality information on their national wheat crop and also have it available to the public.

METHODS

GRADING:

Full grading was done in accordance with the Regulations relating to the grading, packing and marking of wheat intended for sale in the Republic of South Africa (No. R. 905 of 10 July 1998 as amended by Nos. R. 1421 of 6 November 1998, R. 876 of 14 September 2001 and R. 979 of 19 July 2002, R. 1210 of 29 August 2003 and Dispensation: Reference No. 21/4/1/1 and Serial No. 791 of 25 July 2003).

Hectolitre mass, screenings, protein and falling number were determined. The determination of deviations relating to wheat kernels comprised foreign matter including gravel, stones, turf and glass; other grain and unthreshed ears; damaged kernels including heat-damaged kernels, immature kernels, insect-damaged kernels and sprouted kernels; heavily frost-damaged kernels; field fungi; storage fungi; ergot; noxious seeds; possible presence of undesirable odours and live insects.

Hectolitre mass means the mass in kilogram per hectolitre. Hectolitre mass provides a measure of the bulk density of the grain and is also useful as a guide to grain soundness and potential milling extraction.

Screenings means all material that passes through a standard sieve. A standard sieve is a hand sieve which consists of a slotted, stainless steel sieve with a thickness of 1,0 mm, mounted in durable plastic, with apertures 1,8 mm wide and 12,7 mm long, which fits into an aluminum pan with a solid bottom, and has a inner diameter of 300 mm and an outer diameter of 302,5 mm.

Damaged kernels means wheat kernels and pieces of wheat kernels -

- (a) which have been damaged by insects;
- (b) which have been distinctly discoloured (orange-brown, dark brown or black) by external heat or as a result of heating caused by internal fermentation in wheat with an excessive moisture content, excluding wheat kernels in respect of which the discolouration is

confined to the germ end;

- (c) which are immature and have a distinctly green colour; and
- (d) in which germination has proceeded to such an extent that the skin covering the embryo has been broken or the developing rootlets are clearly visible.

THOUSAND KERNEL MASS:

This is the weight in grams of one thousand kernels of grain and provides a measure of grain size and density. This determination does not include kernels that are broken or chipped.

FALLING NUMBER MILLING:

At least 300 g of wheat is cleaned by using the standard 1,8 mm sieve and by removing coarser impurities by hand. The sample is then milled on the falling number hammer mill fitted with a 0,8 mm screen.

PROTEIN:

The Dumas combustion analysis technique is used, according to AACC method 46-30, 1999.

This method prescribes a generic combustion method for the determination of crude protein. Combustion at high temperature in pure oxygen sets nitrogen free, which is measured by thermal conductivity detection. The total nitrogen content of the flour sample is determined and converted to equivalent protein by multiplication with a factor of 5.7 to obtain the protein content.

FALLING NUMBER:

This method is based upon the rapid gelatinization of an aqueous suspension of meal or flour in a boiling water bath and subsequent measurement of the liquefaction of the starch paste by the alpha-amylase in the sample. The method measures the alpha-amylase activity.

ICC Standard No.107/1, 1995 is used to determine the falling number. Only the altitude-corrected value is reported.

QUADROMAT MILLING:

Cleaned wheat samples are conditioned by adding 3 ml water per 100 g wheat, 18 hours prior to milling. The samples are then milled on the Quadromat junior laboratory mill.

MIXOGRAPH:

A 35 g mixograph is used. The amount of water added to the flour is adjusted according to the flour protein content. Industry Accepted Method 020 based on AACC method 54-40A, 1999 is followed.

Mixogram peak time is the time measured in minutes that a dough takes to reach its maximum consistency or first indication of dough weakening. The peak time is a measure of optimum dough development and thus a measure of protein quality.

Mixogram tail height at 6 minutes is the distance in millimetres measured from the base line of the paper at 6 minutes to the graph centre point at 6 minutes. This figure is an indication of the weakening effect of the dough. Higher values indicate flours that are more tolerant to mixing.

BÜHLER MILLING:

Cleaned wheat samples are damped to between 15,0 % and 16,0 % moisture according to the wheat moisture and kernel hardness and allowed to stand for 20 hours. Samples are then milled on a standard Bühler MLU 202 mill and passed through a bran finisher.

BÜHLER EXTRACTION:

The extraction represents the flour yield after milling plus flour obtained from bran that passed through a bran finisher. Flour extraction is calculated from the mass of the total products. Bühler MLU 202 mill set for South African wheat, mill settings and sieve sizes deviate from AACC method 26-21A, 1999.

COLOUR:

The Kent Jones colour is determined by following FTP Method No. 0007/3, 7/1991.

This method determines the influence of the branny material present in flour by measuring reflectance with a light source in the green band of the light spectrum. The lower the Kent Jones colour, the brighter the flour.

FARINOGRAPH:

AACC method 54-21, 1999 constant flour weight procedure is followed, using 300 g of flour on a 14 % moisture basis.

The **farinograph** measures and records the resistance of a dough to mixing, as it is formed from flour and water, developed and broken down. The dough is subjected to a prolonged, relatively gentle mixing action at a constant temperature.

The **water absorption** is the amount of water required for a dough to reach a definite consistency (500 Brabender units). The amount of water added to the flour is expressed as a percentage of the flour mass and reported on a 14 % moisture basis.

The **development time** is the time from the beginning of water addition until the dough reaches its optimum consistency and the point immediately before the first indication of weakening. A long mixing time can be associated with flours that have a high percentage of gluten-forming proteins.

The **stability** is the time during which the top of the curve intercepts a horizontal line through the centre of the curve. This gives an indication of the dough's tolerance to mixing: the longer the stability, the longer the mixing time that the dough can withstand. A dough with a longer stability can also withstand a longer fermentation period.

The **mixing tolerance index value** is the difference, in Brabender units, between the top of the curve at the peak and the top of the curve measured 5 minutes after the peak is reached. The value gives an indication of the extent to which breakdown of the dough occurs. The higher the value, the more and the quicker the breakdown of the dough occurs. This value is similar to the mixogram tail height.

EXTENSOGRAPH:

ICC Standard No. 114/1, 1992 is followed.

The **strength** gives an indication of the total force (work) needed to stretch the dough and is represented by the area under the curve.

The **maximum height** gives an indication of the dough's resistance to stretching and is measured as the mean of the maximum heights of the curves of the two test pieces.

The **extensibility** is the mean length at the base of the 2 curves and indicates the stretchability of the dough.

ALVEOGRAPH:

ICC Standard No.121, 1992 is followed.

The **alveograph** measures the resistance of the dough to stretching and also how extensible the dough is. The **alveograph** stretches the dough in more than one direction (as is happening during proofing), whereas the extensograph stretches the dough in only one direction.

Strength: The area under the curve gives an indication of the dough strength.

Stability (P): Obtained by multiplying the maximum height of the curve with a constant factor of 1.1. This value is an indication of the resistance of the dough to extension.

Distensibility (L): The length of the curve, measured along the base line, gives an indication of the extensibility of the dough and also predicts the handling characteristics of the dough.

P/L-value: This ratio is obtained by dividing the P-value by the L-value, thus providing an

approximate indication of the shape of the curve that combines stability and extensibility.

100 g BAKING TEST:

This procedure, according to Industry Accepted Method 022 based on AACC Method 10-10B, 1999, provides an optimized bread-making method for evaluating bread wheat flour quality and a variety of dough ingredients by a straight-dough method in which all ingredients are incorporated in the initial mixing step.

Keys for the evaluation of the 100g Baking test:

- 0 - *Excellent*
- 1 - *Very Good*
- 2 - *Good*
- 3 - *Questionable*
- 4 - *Poor*
- 5 - *Very Poor*
- 6 - *Extremely Poor*

Please note:

This 100 g Baking test evaluation does not give an indication of the baking quality of the flour, but refers to the relationship between the protein content and the bread volume.

MYCOTOXIN ANALYSES

Mycotoxins are natural contaminants of food and feedstuffs with serious implications for public health and economics, in particular with relation to the international food trade.

The mycotoxin analyses were carried out in accordance with the Vicam immunoaffinity column technique using the different Vicam instruction manuals for the different mycotoxins. Detection of the toxins was done on a fluorometer. Thirty samples of the 480 wheat crop samples were tested for aflatoxin, deoxynivalenol and ochratoxin.
