## COMMERCIAL WHEAT QUALITY FOR THE 2009/2010 SEASON

### Acknowledgements

With gratitude to:

- The Winter Cereal Trust for its financial support in conducting this survey.
- The Grain Silo Industry and its members for their cooperation in providing the samples to make this survey possible.
- The National Chamber of Milling and its members for providing samples of wheat delivered directly to the mills.

### Introduction

The final wheat production of 1 958 000 tons for the 2009/2010 season, was 8 % lower than the previous season's 2 130 000 tons. This is 3 % lower than the 10 year average of 2 017 835 tons (2000/2001 to 2009/2010 seasons). A total area of 642 500 hectares was utilized for wheat production. (Figures obtained from the Crop Estimates Committee).

The whole wheat protein average was 11.7 % compared to the 12.0 % of the previous season, which is also the same as the ten year average. The average hectolitre mass was 79.9 kg/hl. This value includes the addition of 2 kg/hl to all individually obtained values as per the Hectolitre mass Dispensation (please see Methods page 53). The percentage of samples in this survey graded as B1 increased from 27 % the previous season to 33 % this season.

High levels of rainfall during harvesting in several parts of the Swartland in the Western Cape resulted in sprouting and low falling numbers. No major problems were experienced with the climatic conditions and rainfall patterns in the rest of the production regions.

Differences in the flour and dough qualities between the winter rainfall, summer rainfall and irrigation areas were observed as in previous seasons. The overall flour and dough quality was average to good.

The mixograph peak time of flour milled on the Quadromat mill averaged 2.9 minutes, varying from 2.5 minutes in the Western Cape to 3.3 minutes in the Free State. The straight-dough optimized 100-gram baking test showed little variation in volume according to the protein content. The average relationship between protein and bread volume was excellent.

During the harvesting season, a representative sample of each delivery of wheat is taken according to the prescribed wheat regulation. A sub-sample of each of these grading samples is collected in a bin according to grade and class per silo bin at each silo. This composite bin sample is then divided and a 5 kg sample is sent to the Southern African Grain Laboratory (SAGL) for the annual wheat crop quality survey. SAGL selected 480 samples representing the production of wheat in all the different production regions.

The samples, are fully graded and thousand kernel mass is done. Small samples are milled on the quadromat mill, followed by a mixogram analysis.

Cultivar identification is done on these samples and sale figures of seed sold by the commercial grain silo owners are obtained.

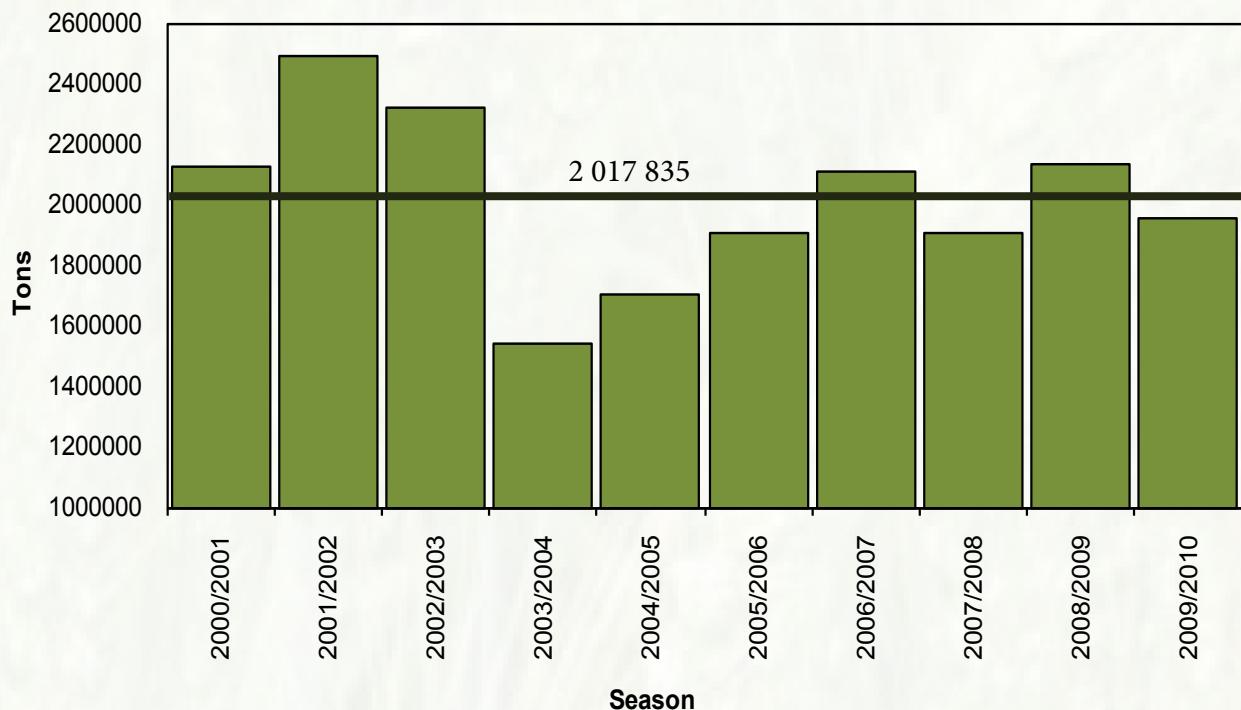

Composite samples are made up per class and grade for each production region and milled on the Bühler mill. Rheological tests, namely a mixogram, farinogram, alveogram, extensogram and 100-gram baking test, are then performed.

The results (as averages per region) are made available weekly on the SAGL website ([www.sagl.co.za](http://www.sagl.co.za)) as soon as the first samples are received. The hard copy report is available from June each year (with the option to download the report from the website).

Summaries comparing the quality of the local wheat for the 2007/2008 and 2009/2010 as well as the 2008/2009 and 2009/2010 seasons are provided.

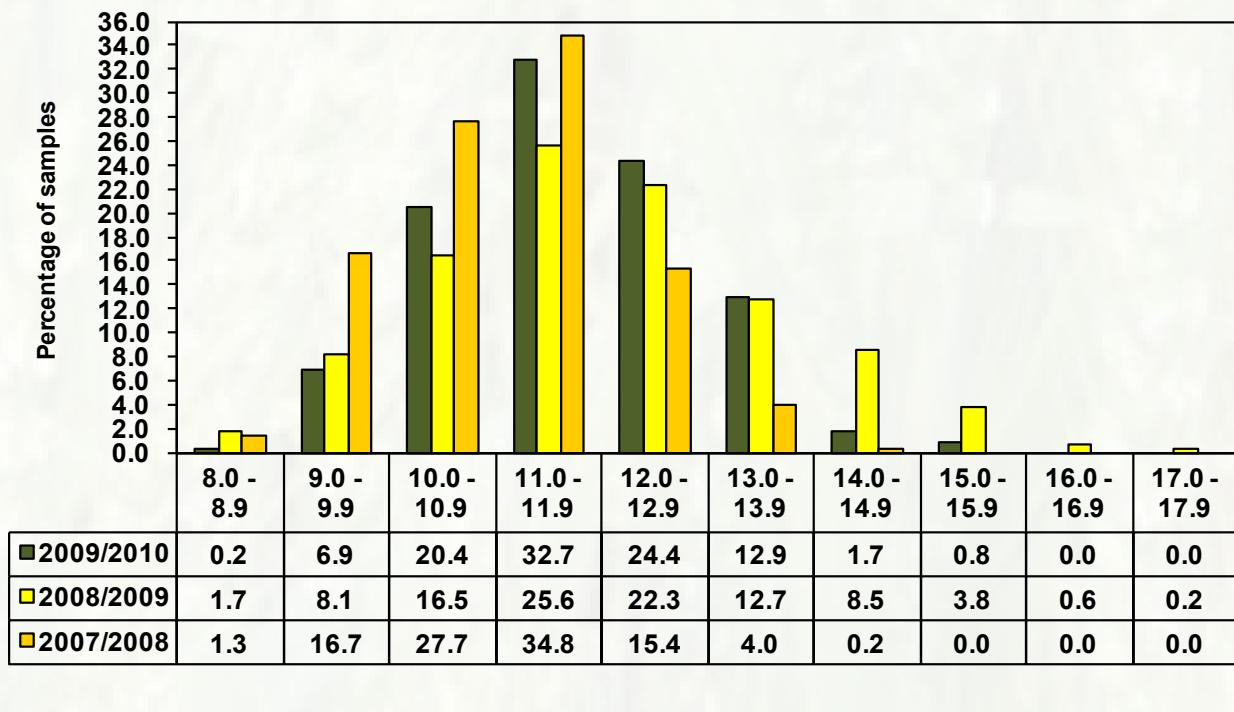

## WHEAT PRODUCTION IN THE RSA OVER THE LAST 10 SEASONS

### Wheat Production RSA

### DIFFERENCES IN THE DISTRIBUTION OF PROTEIN CONTENT OVER THE LAST 3 SEASONS

### Distribution of protein content

## Crop quality of the 2009/2010 season

The protein graph of the wheat produced in the 2009/2010 season showed a normal distribution around the 11.0 - 11.9 % protein level (see page 2). The highest percentage of samples (32.7 %) had protein contents ranging from 11.0 - 11.9 %. The second highest percentage of 24.4 % was for protein contents 12.0 - 12.9 % and thirdly 20.4 % for 10.0 - 10.9 % protein content. The irrigation areas had the highest average protein content of 12.2 % and the winter rainfall area the lowest with 11.1 %.

No significant differences were observed in the average hectolitre mass between the different production regions. The weighted average thousand kernel mass of 39.1 g was almost 1 g higher than the previous season.

The weighted average screenings (1.8 mm sieve) was 1.63 % compared to the 1.72 % in the 2008/2009 season.

The weighted average falling number was 367 seconds. Twenty eight samples gave falling number values of less than 250 seconds and of these, eighteen had falling number values lower than 220 seconds. These samples were mainly from the Western Cape (60 %).

The weighted mixogram peak time on flour from the Quadromat mill averaged 2.9 minutes, equal to the ten year average. The weighted mixogram peak time of the flour from the Bühler mill averaged 2.6 minutes.

The weighted average Bühler extraction was 74.7 %, with a weighted average Kent Jones colour of -2.2 KJ.

The farinogram had a weighted average water absorption of 61.0 % (61.1 % the previous season) and a weighted average development time of 3.5 minutes (4.0 minutes last season). The weighted average alveogram strength was 35.5 cm<sup>2</sup> and the weighted average P/L value 1.17 (38.0 cm<sup>2</sup> and 0.90 the previous season). The weighted average extensogram strength was 83 cm<sup>2</sup> (90 cm<sup>2</sup> previous season).

The loaves baked using the 100 g straight-dough optimized bread making method, which refers to the relationship between the protein content and the bread volume, was evaluated and scored from "Excellent" to "Very Good".

## Wheat grades

The 480 representative crop samples were graded as follows: 33 % was graded B1, 29 % was graded B2, 17 % was graded B3, 6 % was graded B4, 12 % UT (Utility Grade) and 3 % COW (Class Other Wheat). The adjustment of the hectolitre mass results by adding 2 kg/hl according to the Dispensation (please see Methods page 53), contributed to the increase in the percentage samples graded B1, compared to the 2008/2009 season.

Grade B1 wheat in the Free State province amounted to 45 % (47 % the previous season) and grade B1 in other summer rainfall and irrigation areas amounted to 36 % (31 % in the previous season). In the irrigation areas 43 % (21 % in the previous season) of the wheat graded as B1 and in the Western Cape Province 15 % graded as B1 (11 % in the previous season).

## Cultivars

In the Western Cape, SST 027 dominated the market (36 %). SST 015 (29 %) and SST 88 (21 %) were also popular cultivars. The Western Cape produced 35 % of all wheat grown in South Africa during the 2009/2010 season.

Regions 21 to 24 of the Free State were dominated by PAN 3120 (24 %). Elands dominated regions 25 to 28 (36 %). SST 835, PAN 3118, SST 356, Matlabas and Gariep were also popular cultivars.

Farmers in the Vaal and Orange River areas preferred SST 835 (39 %), CRN 826 (19 %) and Duzi (15 %).

The most preferred cultivar in the North West was SST 835 (47 %), followed by SST 843 (15 %) and CRN 826 (13 %).

In Limpopo, Gauteng and Mpumalanga SST 835 (41 %) was the dominant cultivar followed by Duzi (23 %).

The above information was calculated from the cultivar identification done on all 480 crop samples.

## Mycotoxins

Mycotoxins, as secondary metabolites of moulds or fungi, can cause toxic effects in humans and animals consuming contaminated foods or feeds. Thirty samples (representing different regions) were selected randomly for mycotoxin analyses. These samples were tested for aflatoxin, deoxynivalenol and ochratoxin A.

The highest Aflatoxin content found was 4 ppb ( $\mu\text{g}/\text{kg}$ ). In accordance with Act 54 of 1972, Foodstuffs, Cosmetics and Disinfectants, the allowable level of total aflatoxin is 10 ppb ( $\mu\text{g}/\text{kg}$ ). In accordance with Act 36 of 1947, Fertilizers, Farm Feeds, Agricultural and Stock Remedies, the allowable level of total aflatoxin is 10 to 50 ppb ( $\mu\text{g}/\text{kg}$ ).

The average deoxynivalenol (DON) content was 0.05 ppm ( $\text{mg}/\text{kg}$ ) with the highest value being 0.48 ppm.

The average ochratoxin A content was 0.17 ppb ( $\mu\text{g}/\text{kg}$ ) with the highest report value being 1 ppb.

## Quantity of imported wheat for the 2008/2009 season (previous season)

During the 2008/2009 season, 1 201 053 tons of wheat were imported for RSA. The biggest quantity was imported from Germany, namely 518 435 tons, followed by Argentina with 368 739 tons, USA with 113 434 tons, Australia with 74 714 tons, Canada with 54 831 tons, Brazil with 44 366 tons, then Ukraine with 13 521 tons and Poland with 13 013 tons. (SAGIS web site).

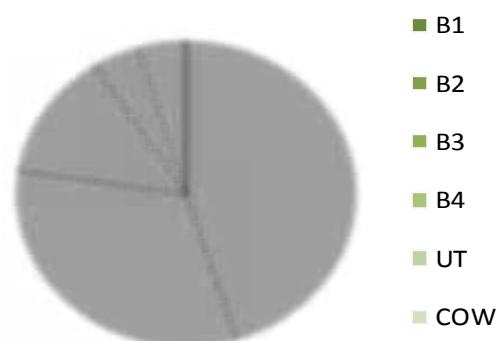

For grading as well as dough and baking quality of the imported wheat, please refer to pages 56 to 67. No samples were received for analysis from Poland and Ukraine.

## Wheat class and grades per production area

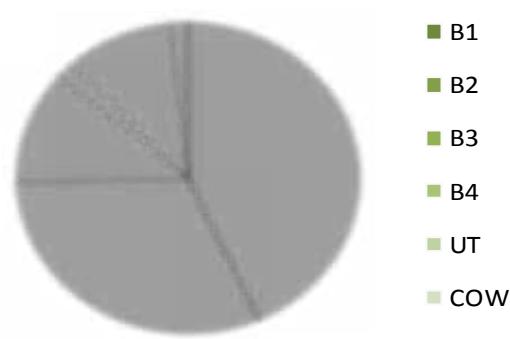

**Number of samples per class and grade in the winter rainfall area**

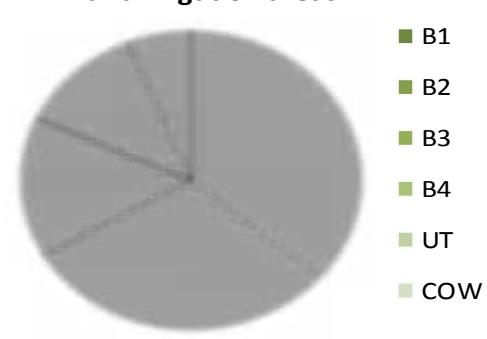

**Number of samples per class and grade in the summer rainfall area**

**Number of samples per class and grade in the irrigation areas**

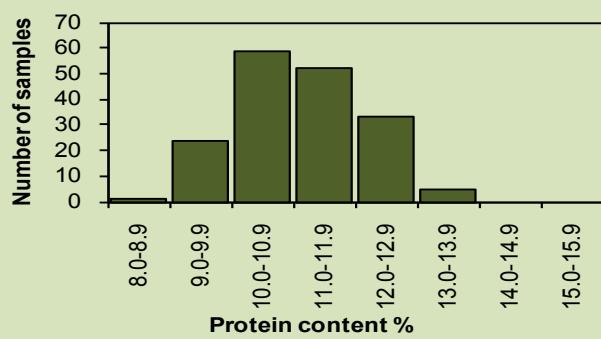

**Number of samples per class and grade in the other summer rainfall and irrigation areas**

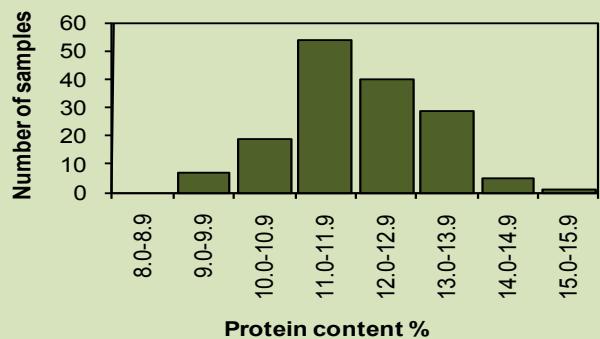

## Protein distribution graphs per production area

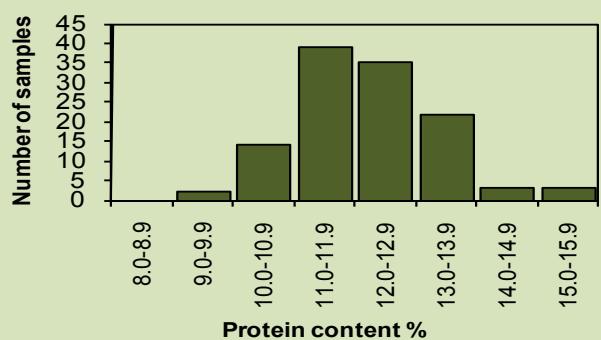

**Protein distribution of wheat in the winter rainfall area**

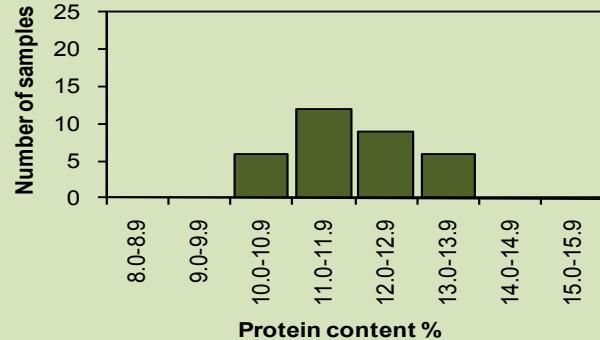

**Protein distribution of wheat in summer rainfall area**

**Protein distribution of wheat in the irrigation areas**

**Protein distribution of wheat in other summer rainfall and irrigation areas**

## WEIGHTED AVERAGE QUALITY OVER 10 SEASONS

\* Includes addition of 2 kg/hl according to Hectolitre mass Despensation.

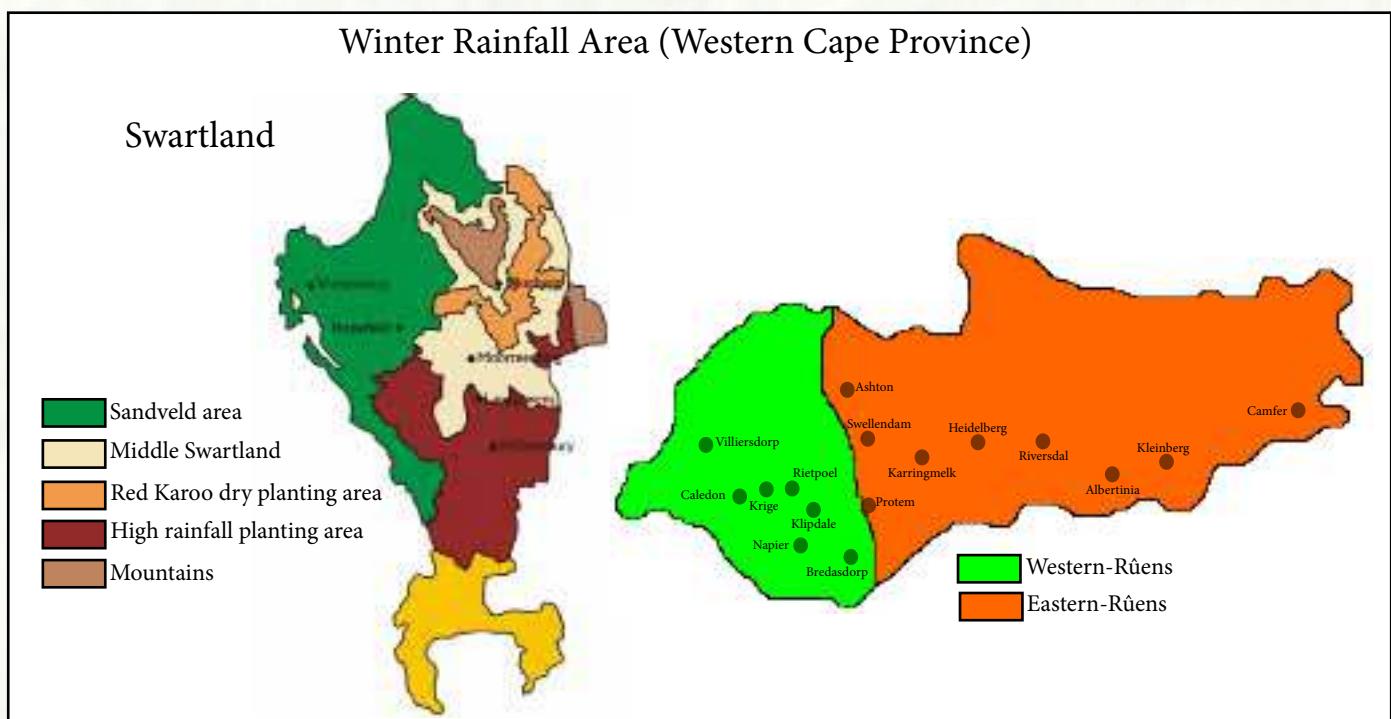

## REGIONAL QUALITY

### WINTER RAINFALL AREA (Western Cape)

Production regions 1 to 6 fall within the winter rainfall area (Western Cape Province). Region 1 is Namaqualand, regions 2 - 4 are the Swartland area and regions 5 and 6 the Rûens area. The Western Cape had the highest production of all the provinces this season, namely 675 000 tons (35 %) (CEC).

The hectolitre mass averaged 79.3 kg/hl. The thousand kernel mass averaged 39.9 gram, which is lower than the previous season's 42.1 gram. The average falling number was 353 seconds. The average protein content of 11.11 % (12 % mb) was the lowest of the different production areas.

Conditions for crop production were generally favourable in the winter rainfall area. Parts of the Swartland however experienced heavy rainfall during harvesting which resulted in pre-harvest sprouting and therefore low falling numbers.

The screenings of 2.02 % was higher than the previous season's 1.72 %. The Bühler extraction averaged 74.2 % (average of wheat grades B1 to B4, UT and COW) and the average colour of the flour was -2.2 KJ units. This colour indicates a very white flour that is preferred by millers and bakers.

The mixogram peak time (Quadromat mill) averaged 2.5 minutes. The average farinogram absorption was 60.5 %. The average alveogram strength was 30.4 cm<sup>2</sup> and the average strength on the extensogram was 64 cm<sup>2</sup>. The alveogram strength in the Free State was 35.9 cm<sup>2</sup> and in the irrigation areas 40.0 cm<sup>2</sup>.

The 100-gram baking test showed an excellent relationship between protein content and bread volume.

## SUMMER RAINFALL AREA

(Free State)

Production regions 21 to 28, which fall within the Free State Province, had the second highest production, namely 622 750 tons (32 %) (CEC).

The 2.7 tons/ha average yield in the Free State was higher than the 2.0 tons/ha of the previous season.

Planting conditions were good due to good rainfall, in the late summer. Climatic conditions were favourable during harvesting.

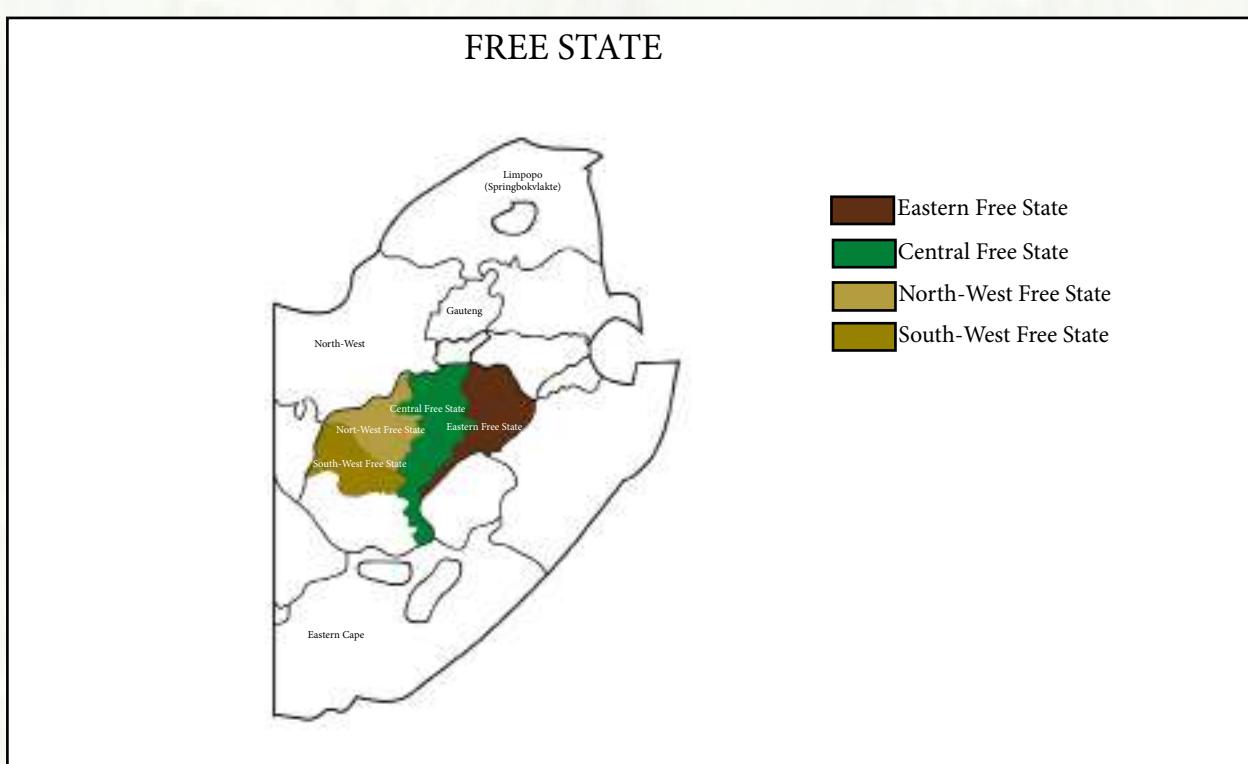

The average hectolitre mass was 80.0 kg/hl. The physical characteristic thousand kernel mass (38.4 g) was higher than the previous season's 34.5 g. The average screenings was 1.25 %. The average protein content decreased from 13.40 % the previous season to 11.93 % (12 % mb) this season. Although the average falling number was 354 seconds, seven samples gave falling numbers lower than 250 seconds and three samples were below 220 seconds.

The mixogram (Quadromat) peak time of 3.3 minutes was the same as the previous season, giving the Free State the longest average mixogram peak time of the different production areas.

The average Bühler extraction percentage in the Free State was 75.6 % (75.0 % previous season). The Kent Jones flour colour was -2.3 KJ units (-1.1 KJ units in previous season).

The average farinogram water absorption was 61.1 %, a little lower than the previous season but more or less the same as the other regions. An average alveogram strength of 35.9 cm<sup>2</sup> and an extensogram strength of 88 cm<sup>2</sup> were reported.

The 100-gram baking test showed that the relationship between protein content and bread volume ranged from excellent to very good between the different grades.

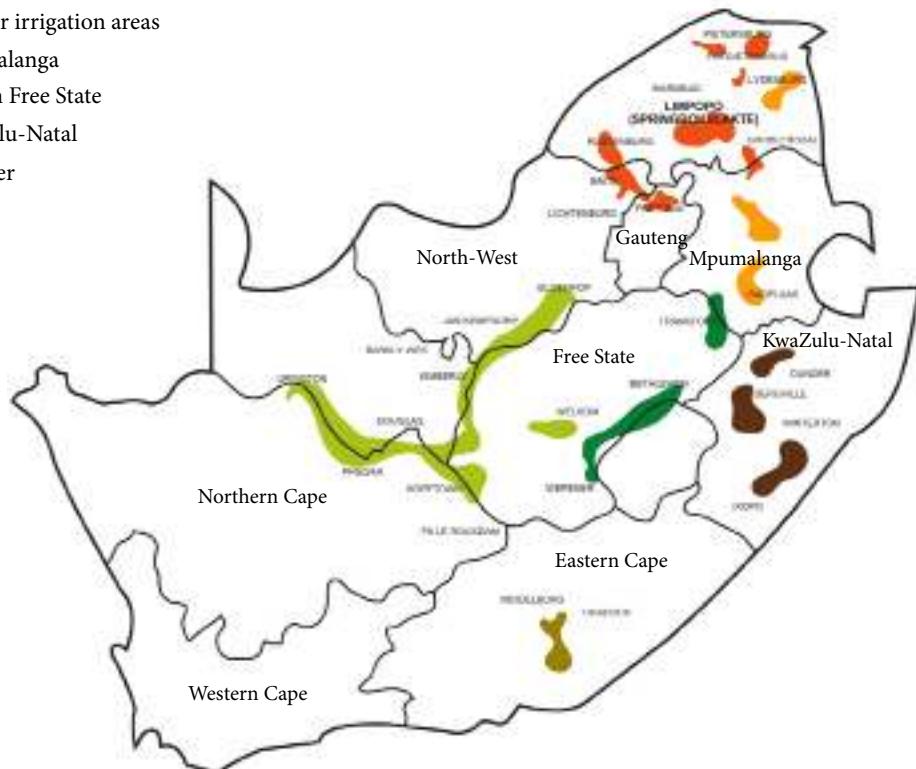

## IRRIGATION AREAS

(Northern Cape, North West (plus other irrigation areas))

Irrigation areas in South Africa

- Cooler irrigation areas
- Warmer irrigation areas
- Mpumalanga
- Eastern Free State
- KwaZulu-Natal
- Visrivier

Production regions 7, 10 - 12, 14 - 20 and 36 falls within the irrigation areas. These areas produced 469 000 tons of wheat this season (24 % of total production) with an average yield of 5.3 tons/hectare.

The average hectolitre mass was 80.6 kg/hl and the thousand kernel mass was 38.6 g (37.0 g the previous season). The average falling number was 404 seconds. The average screenings was 1.75 % and the protein averaged 12.18 % (12 % mb).

The average mixogram (Quadromat) peak time was 2.6 minutes which was more or less the same as the previous season.

The average Bühler extraction percentage was 73.9 (76.5 % during the previous season), with an average flour colour of -2.2 KJ units.

The average farinogram water absorption was 61.6 % (60.0 % during previous season), with an average farinogram development time of 3.3 minutes.

The average alveogram strength was 40.0 cm<sup>2</sup> and the average P/L 1.68 (36.8 cm<sup>2</sup> and 0.57 respectively the previous season).

The average extensogram strength was 92 cm<sup>2</sup>. The relationship between protein content and bread volume (with the 100-gram baking test) was shown to be very good.

## OTHER SUMMER RAINFALL AND IRRIGATION AREAS (Mpumalanga, Limpopo and Gauteng)

Other summer rainfall regions, excluding the Free State, are mainly regions 30, 32, 33 (Mpumalanga), 34 (Gauteng) and 35 (Limpopo). They produced in total 153 050 tons during this season (8 % of the total production).

The average hectolitre mass was 79.8 kg/hl and the average thousand kernel mass was 40.6 g (39.5 g the previous season).

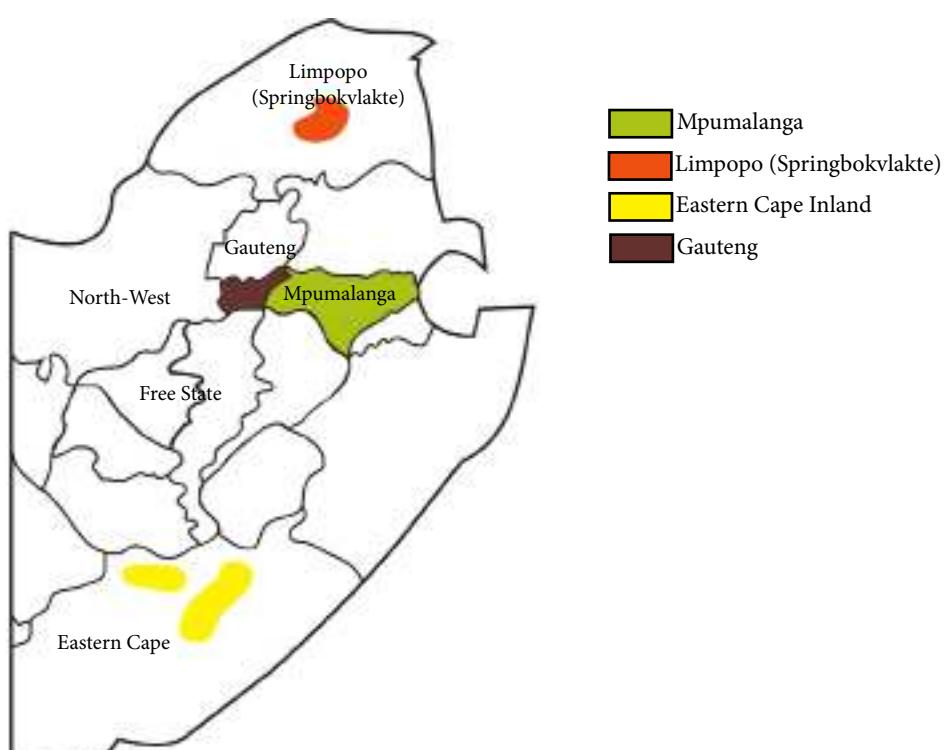

The average falling number was 370 seconds, with the average percentage screenings 1.00 %. The average protein content was 11.83 % (12 % mb), which is similar to the previous year.

The average mixogram (Quadromat) peak time was 3.1 minutes (3.0 minutes the previous season).

The average Bühler extraction was 76.2 %, with an average colour of -2.1 KJ units (76.2 % and -1.5 KJ units the previous season). The farinogram average water absorption was 60.1 % (60.8 % the previous season) and had an average development time of 3.8 minutes.

The average alveogram strength was 35.8 cm<sup>2</sup>, with an average P/L value of 0.77, and the average extensogram strength was 93 cm<sup>2</sup>.

The 100-gram baking test showed an excellent relationship between protein content and bread volume.

Regional maps with gratitude to ARC - Small Grain Institute

## South African Winter Cereal Production

Wheat is by far the biggest winter cereal crop planted in South Africa. Other winter crops are barley for malting purposes and canola. Summer field crops are better suited for the South African climatic conditions. Maize has the largest crop size of the different crops, followed by wheat, then soya-beans, sunflower seed, sorghum, barley, groundnuts, dry beans and canola.

South Africa (made up of nine provinces) is divided into 36 crop production regions with wheat planted in about 32 of these regions. These production regions are described on pages 16 to 44 (in the header of the left page) giving the specific intake silo names for each region.

The three main wheat producing provinces are Western Cape (winter rainfall), Free State (summer rainfall) and the Northern Cape (irrigation). A fourth province worth mentioning is the North-West (mainly irrigation).

The Western Cape province produced 675 000 tons and the Free State province followed with 622 750 tons. (Seventh estimate by the Crop Estimates Committee, CEC). These two provinces were responsible for 67 % of the total wheat produced.

The yield in the main production areas ranged from 6.3 tons per hectare in the Northern Cape (irrigation area), 2.7 tons per hectare in the Free State and 2.3 tons per hectare for the Western Cape. Gauteng gave a yield of 6.4 tons per hectare, followed by North West with 5.7 tons per hectare and Limpopo and Mpumalanga both with 5.5 tons per hectare. KwaZulu-Natal and the Eastern Cape yielded 5.0 and 4.0 tons per hectare respectively. See graph on page 13.

The local production is not sufficient for domestic requirements and South Africa has to import wheat to meet its domestic consumption of approximately 2.9 million tons every year.

South Africa has three major wheat-breeding programs. The South African breeders can only release a new cultivar or an introduction cultivar if it has better agronomical as well as better flour quality characteristics than the cultivars planted commercially in a specific area. Producers continuously strive to improve the wheat yield and quality by selecting the best cultivars for commercial production in a specific area. Grading standards are also set high to ensure adequate quality control.

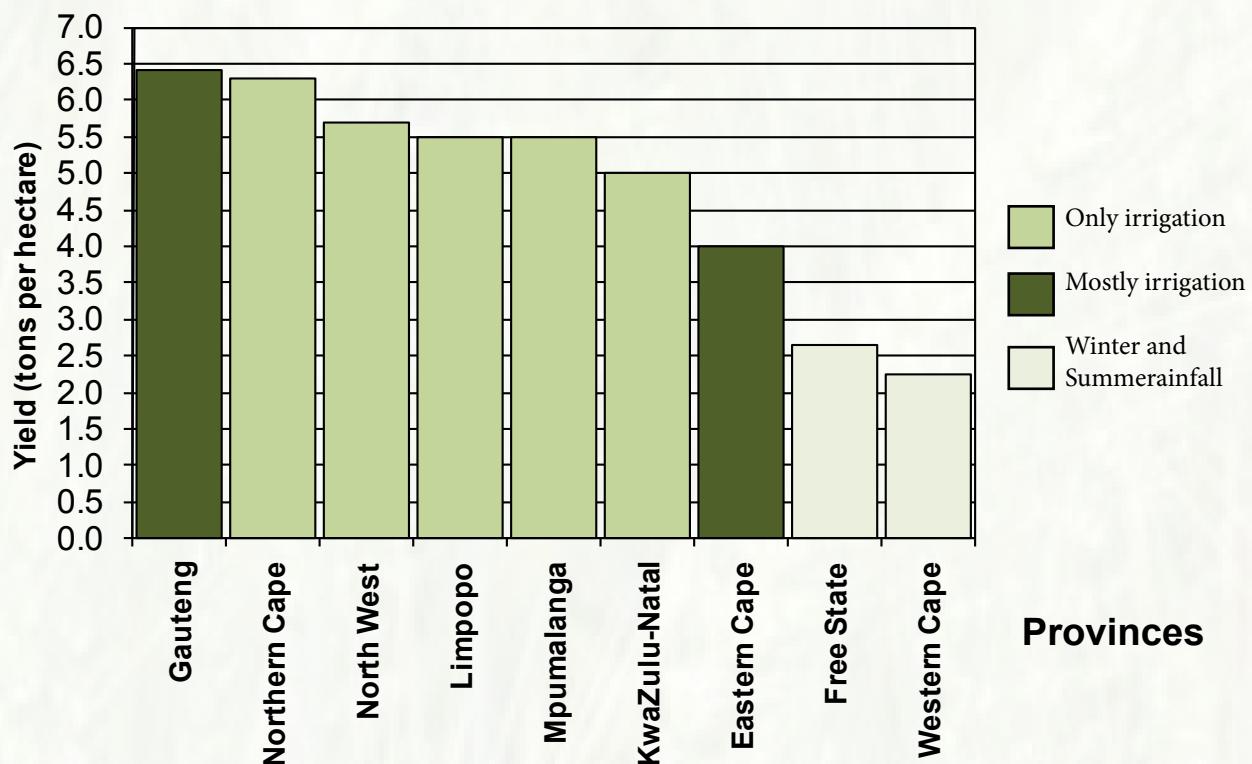

### Imported wheat (1 October 2008 - 30 September 2009) (Previous season)

The quality of all wheat imported into South Africa is also monitored by the SAGL. The range of analyses done on the local crop for the purpose of this survey are also done on the imported wheat. These results may only be made available at the end of each season.

Pages 56 to 67 of this report contain summaries of wheat imported from specific countries during the 2008/2009 season. This imported wheat quality is compared to a summary of the local crop quality for the same season.

The quality of the Australian and Canadian flour milled from wheat imported during the 2008/2009 season were better than the local wheat flour quality. The Argentinian and German flour were not as good as the quality of the local flour of the 2008/2009 season, while the Brazilian and American flour were noticeably weaker than the local flour.

## Average yield per province (Irrigation versus summer and winter rainfall areas)

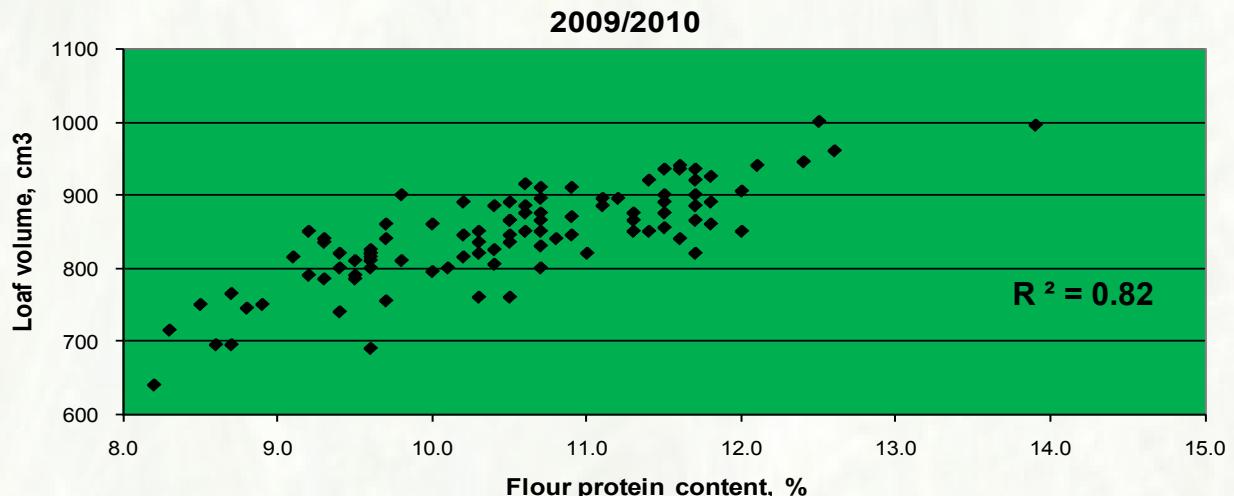

(Based on figures obtained from CEC)

### Comparison of protein content vs loaf volume

### Comparison of wet gluten content vs loaf volume

### Comparison of protein content vs dry gluten content

## Comparison of Flour Quality over the last four seasons

Flour Quality 2009/2010 season			
Flour protein (12 % mb)	10.5	Farinogram water abs. (%)	61.0
Bread volume 100g (cm <sup>3</sup> )	843	Farinogram dev. time (min.)	3.5
Mixogram (Bühler) peak time (min)	2.6	Alveogram strength (cm <sup>2</sup> )	35.5
Extensogram strength (cm <sup>2</sup> )	83	Alveogram P/L	1.17

Flour Quality 2008/2009 season			
Flour protein (12 % mb)	11.1	Farinogram water abs. (%)	61.1
Bread volume 100g (cm <sup>3</sup> )	902	Farinogram dev. time (min.)	4.0
Mixogram (Bühler) peak time (min)	2.6	Alveogram strength (cm <sup>2</sup> )	38.0
Extensogram strength (cm <sup>2</sup> )	90	Alveogram P/L	0.90

Flour Quality 2007/2008 season			
Flour protein (12 % mb)	10.8	Farinogram water abs. (%)	60.8
Bread volume 100g (cm <sup>3</sup> )	827	Farinogram dev. time (min.)	3.6
Mixogram (Bühler) peak time (min)	2.8	Alveogram strength (cm <sup>2</sup> )	41.9
Extensogram strength (cm <sup>2</sup> )	97	Alveogram P/L	0.94

Flour Quality 2006/2007 season			
Flour protein (12 % mb)	10.6	Farinogram water abs. (%)	61.4
Bread volume 100g (cm <sup>3</sup> )	816	Farinogram dev. time (min.)	3.4
Mixogram (Bühler) peak time (min)	2.6	Alveogram strength (cm <sup>2</sup> )	36.8
Extensogram strength (cm <sup>2</sup> )	82	Alveogram P/L	0.93

# METHODS

## GRADING:

Full grading was done in accordance with the Regulations relating to the grading, packing and marking of wheat intended for sale in the Republic of South Africa (No. R. 905 of 10 July 1998 as amended by Nos. R. 1421 of 6 November 1998, R. 876 of 14 September 2001 and R. 979 of 19 July 2002, R. 1210 of 29 August 2003 and Dispensations: Reference No. 21/4/1/1 and Serial No. 791 of 25 July 2003 and Reference No. 20/4/14/1 of 14 April 2009).

Hectolitre mass, screenings, protein and falling number were determined. The determination of deviations relating to wheat kernels comprised foreign matter including gravel, stones, turf and glass; other grain and unthreshed ears; damaged kernels including heat-damaged kernels, immature kernels, insect-damaged kernels and sprouted kernels; heavily frost-damaged kernels; field fungi; storage fungi; ergot; noxious seeds; possible presence of undesirable odours and live insects.

Hectolitre mass means the mass in kilogram per hectolitre and was determined by means of the Two-level funnel method.

An ammended grading regulation for wheat, in which the Two-level funnel method for the determination of hectolitre mass is replaced with any suitable instrument complying with ISO Standard 7971-3, will come into effect on 1 October 2010.

From 1 October 2009 to 30 September 2010, Dispensation Ref. No. 20/4/14/1 and dated 14 April 2009, will be applicable according to which regulation 14 (1) (g) of the current grading regulation document will be substituted by the following equation:

$$\text{Hectolitre mass} = \frac{\text{Mass (g) of wheat in a 500ml bucket} + 2\text{kg/hl}}{5}$$

Hectolitre mass provides a measure of the bulk density of grain and is also useful as a guide to grain soundness and potential milling extraction.

Screenings means all material that passes through a standard sieve. A standard sieve is a hand sieve which consists of a slotted, stainless steel sieve with a thickness of 1,0 mm, mounted in durable plastic, with apertures 1,8 mm wide and 12,7 mm long, which fits into an aluminum pan with a solid bottom, and has a inner diameter of 300 mm and an outer diameter of 302,5 mm.

Damaged kernels means wheat kernels and pieces of wheat kernels -

- (a) which have been damaged by insects;
- (b) which have been distinctly discoloured (orange-brown, dark brown or black) by external heat or as a result of heating caused by internal fermentation in wheat with an excessive moisture content, excluding wheat kernels in respect of which the discolouration is confined to the germ end;
- (c) which are immature and have a distinctly green colour; and
- (d) in which germination has proceeded to such an extent that the skin covering the embryo has been broken or the developing rootlets are clearly visible.

## THOUSAND KERNEL MASS:

This is the weight in grams of one thousand kernels of grain and provides a measure of grain size and density. This determination does not include kernels that are broken or chipped.

## FALLING NUMBER MILLING:

At least 300 g of wheat is cleaned by using the standard 1,8 mm sieve and by removing coarser impurities by hand. The sample is then milled on the falling number hammer mill fitted with a 0,8 mm screen.

## MOISTURE:

ICC Standard No. 110/1, 1976 is used to determine the moisture content of wheat flour. This method determines moisture content as a loss in weight of a sample when dried in an oven at 130°C for 90 minutes or 2 hours for flour and whole wheat flour respectively.

## PROTEIN:

The Dumas combustion analysis technique is used, according to AACC method 46-30.01, 1999.

This method prescribes a generic combustion method for the determination of crude protein. Combustion at high temperature in pure oxygen sets nitrogen free, which is measured by thermal conductivity detection. The total nitrogen content of the flour sample is determined and converted to equivalent protein by multiplication with a factor of 5.7 to obtain the protein content.

## FALLING NUMBER:

This method is based upon the rapid gelatinization of an aqueous suspension of meal or flour in a boiling water bath and subsequent measurement of the

liquefaction of the starch paste by the alpha-amylase in the sample. The method measures the alpha-amylase activity.

ICC Standard No.107/1, 1995 is used to determine the falling number. Only the altitude-corrected value is reported.

#### QUADROMAT MILLING:

Cleaned wheat samples are conditioned by adding 3 ml water per 100 g wheat, 18 hours prior to milling. The samples are then milled on the Quadromat junior laboratory mill.

#### MIXOGRAPH:

A 35 g mixograph is used. The amount of water added to the flour is adjusted according to the flour protein content. Industry Accepted Method 020 based on AACC method 54-40.02, 1999 is followed.

Mixogram peak time is the time measured in minutes that a dough takes to reach its maximum consistency or first indication of dough weakening. The peak time is a measure of optimum dough development and thus a measure of protein quality.

Mixogram tail height at 6 minutes is the distance in millimetres measured from the base line of the paper at 6 minutes to the graph centre point at 6 minutes. This figure is an indication of the weakening effect of the dough. Higher values indicate flours that are more tolerant to mixing.

#### BÜHLER MILLING:

Cleaned wheat samples are damped to between 15,0 % and 16,0 % moisture according to the wheat moisture and kernel hardness and allowed to stand for 20 hours. Samples are then milled on a standard Bühler MLU 202 mill and passed through a bran finisher.

#### BÜHLER EXTRACTION:

The extraction represents the flour yield after milling plus flour obtained from bran that passed through a bran finisher. Flour extraction is calculated from the mass of the total products. Bühler MLU 202 mill set for South African wheat, mill settings and sieve sizes deviate from AACC method 26-21.02, 1999.

#### COLOUR:

The Kent Jones colour is determined by following

FTP Method No. 0007/3, 7/1991. This method determines the influence of the branny material present in flour by measuring reflectance with a light source in the green band of the light spectrum. The lower the Kent Jones colour, the lighter the flour.

#### GLUTEN:

Wheat gluten is the water-insoluble complex protein fraction separated from wheat flours. The ability of wheat flour to produce dough with good gas retaining properties is attributed to gluten.

The gluten content of wheat flour is determined by means of AACC Method 38-12.02, 2000. Wet gluten is washed from meal or flour by an automatic washing apparatus (Glutomatic). Wet gluten is a plastic elastic substance composed principally of two protein fractions. Glutenin, the higher molecular weight fraction, contributes elasticity and Gliadin, the lower molecular weight fraction, provides extensibility.

The wet gluten is dried under standardized conditions in a Glutork to obtain the dry gluten. The total wet and total dry gluten contents are expressed as percentages of the sample on a 14% moisture basis.

#### FARINOGRAPH:

AACC method 54-21.01, 1999 constant flour weight procedure is followed, using 300 g of flour on a 14 % moisture basis.

The farinograph measures and records the resistance of a dough to mixing, as it is formed from flour and water, developed and broken down. The dough is subjected to a prolonged, relatively gentle mixing action at a constant temperature.

The water absorption is the amount of water required for a dough to reach a definite consistency (500 Brabender units). The amount of water added to the flour is expressed as a percentage of the flour mass and reported on a 14 % moisture basis.

The development time is the time from the beginning of water addition until the dough reaches its optimum consistency and the point immediately before the first indication of weakening. A long mixing time can be associated with flours with a high percentage of gluten-forming proteins.

The stability is the time during which the top of the curve intercepts a horizontal line through the centre of the curve. This gives an indication of the dough's tolerance to mixing: the longer the stability, the

longer the mixing time that the dough can withstand. A dough with a longer stability can also withstand a longer fermentation period.

The mixing tolerance index value is the difference, in Brabender units, between the top of the curve at the peak and the top of the curve measured 5 minutes after the peak is reached. The value gives an indication of the extent to which breakdown of the dough occurs. The higher the value, the more and the quicker the breakdown of the dough occurs. This value is similar to the mixogram tail height.

#### EXTENSOGRAPH:

ICC Standard No. 114/1, 1992 is followed.

The strength gives an indication of the total force (work) needed to stretch the dough and is represented by the area under the curve.

The maximum height gives an indication of the dough's resistance to stretching and is measured as the mean of the maximum heights of the curves of the two test pieces.

The extensibility is the mean length at the base of the 2 curves and indicates the stretchability of the dough.

#### ALVEOGRAPH:

ICC Standard No.121,1992 is followed.

The alveograph measures the resistance of the dough to stretching and also how extensible the dough is. The alveograph stretches the dough in more than one direction (as is happening during proofing), whereas the extensograph stretches the dough in only one direction.

**Strength (S):** The area under the curve gives an indication of the dough strength.

**Stability (P):** Obtained by multiplying the maximum height of the curve with a constant factor of 1.1. This value is an indication of the resistance of the dough to extension.

**Distensibility (L):** The length of the curve, measured along the base line, gives an indication of the

extensibility of the dough and also predicts the handling characteristics of the dough.

**P/L-value:** This ratio is obtained by dividing the P-value by the L-value, thus providing an approximate indication of the shape of the curve that combines stability and extensibility.

#### 100 g BAKING TEST:

This procedure, according to Industry Accepted Method 022 based on AACC Method 10-10.03, 1999, provides an optimized bread-making method for evaluating bread wheat flour quality and a variety of dough ingredients by a straight-dough method in which all ingredients are incorporated in the initial mixing step.

Keys for the evaluation of the 100g Baking test:

- 0 - Excellent
- 1 - Very Good
- 2 - Good
- 3 - Questionable
- 4 - Poor
- 5 - Very Poor
- 6 - Extremely Poor

Please note:

This 100 g Baking test evaluation does not give an indication of the baking quality of the flour, but refers to the relationship between the protein content and the bread volume.

#### MYCOTOXIN ANALYSES

Mycotoxins, produced by moulds or fungi, are natural contaminants of food and feedstuffs with serious implications for public health and economics, in particular with relation to the international food trade.

The mycotoxin analyses were carried out using ROSA (Rapid One Step Assay) Quanitative tests, which are lateral flow immuno assay tests, together with the ROSA-M reader for measuring the mycotoxin content. Thirty samples out of the 480 wheat crop samples were tested for aflatoxin, deoxynivalenol and ochratoxin A.

Fungi	Toxin	Method reference
<i>Aspergillus flavus</i>	Aflatoxin	ROSA Quantitative Method, 28 May 2008
<i>Aspergillus ochraceus</i> and several species of <i>Penicillium sp.</i>	Ochratoxin A	ROSA Quantitative Method, 10 September 2008
<i>Fusarium graminearum</i>	Deoxynivalenol (DON)	ROSA Quantitative Method, 11 February 2009
